Background: There is no local data about rickets available in Hazara Division, while clinical experience suggests that problem exists in this area with abundant sunlight. We carried out this study with an objective to determine presence, presentation and predisposing factors of rickets in pediatrics population of Hazara Division. Methods: This study was conducted in Department of Pediatrics, Ayub Teaching Hospital Abbottabad over a twelve months period from July 2003 to July 2004. Children from newborns to fifteen years of age presenting with signs and symptoms of rickets were included and information regarding signs, symptoms, predisposing factors (crowded housing, isolated housing with deficient sun exposure, abundant sun but lack of awareness, malnutrition and antenatal factors) and investigations was recorded on a proforma. Diagnosis was based on clinical signs, radiological changes on x-ray wrist joint and biochemical disturbances in serum levels of alkaline phosphatase, calcium, and inorganic phosphorus. Results: Sixty Children with rickets reported during the study period. The main clinical presentation was in the form of delayed motor milestones in 20 (33.33%) children, recurrent lower respiratory infections in 11 (18.33%) children, recurrent diarrhea in 12 (20%) children, and fits in 3 (5%) children. Skeletal changes on clinical examination were present in 40 (66.6%) children. Radiological signs of rickets were present in 51 (85%) children. Symptoms and signs reverted to normal in all cases after vitamin D supplementation. The apparent risk factors were lack of awareness, malnourishment and antenatal factors. Conclusion: Rickets is common in Hazara Division presenting with variable signs and symptoms, predisposing the childhood population to different illnesses and skeletal deformities. In the presence of abundant sunshine lack of awareness of exposure to sun, malnutrition and antenatal factors may be the important predisposing factors for development of nutritional rickets.

Key words: Rickets, vitamin D deficiency, and malnutrition.

INTRODUCTION
Nutritional rickets is a disorder of growing children due to defective mineralization of newly formed bone matrix because of vitamin D deficiency. An English Physician Dr. Daniel Whistler first described rickets in 1645. In 1861, Trouseau of France linked rickets with lack of sun exposure and faulty diet. At the start of 20th century McCollum discovered vitamin D by the technique of biological analysis of the food. The main source of vitamin D is cutaneous synthesis when 7-dehydrocholesterol in the skin is converted to cholechalciferol (vitamin - D₃) by the sun ultraviolet – B radiations. A number of factors can impair cutaneous synthesis of vitamin D for example decreased sun exposure, increased skin pigmentation and atmospheric pollution. Small amount of vitamin D is also derived from the diet. High intake of the fibers and phytate also decrease intestinal absorption of vitamin D and calcium. Rickets may be subclinical or present with the clinical signs and symptoms, for example, bowed legs, rickety rosary, frontal bossing of the skull, widened wrist and ankle joints, poor growth, delayed motor development, recurrent lower respiratory infections, chronic diarrhea and fits. Radiological findings in rickets include metaphyseal flaring, irregularity and widening of physes.

Hazara Division is an area of Pakistan with ample sunlight throughout the year. However clinical experience shows that rickets is present in this area. Here we are reporting an analysis of rickets cases presenting in a calendar year.

MATERIAL AND METHODS
The study was carried out in the Department of Pediatrics, Ayub Teaching Hospital Abbottabad over a 12 months period from July 2003 to July 2004. All infants and children (indoor and outdoor) presenting with signs and symptoms suggestive of rickets were enrolled in study and information was recorded on a proforma prepared for this purpose. Detailed history from the mother was taken regarding sun exposure, weaning, housing, developmental history, and repeated illnesses in the form of respiratory infections and diarrhea. Nutritional assessment was done according to Gomez classification (table-1). Children with hepatic and renal diseases or on anticonvulsant medicines were excluded from the study. Radiographs of the wrist, serum alkaline phosphatase, serum calcium, and serum inorganic phosphorus were the initial investigations at the time.
of enrollment. Other laboratory investigations included full blood count, liver function test, and renal function test.

RESULTS

During the study period sixty children with rickets were detected which included 47 (78.33%) male and 13 (21.66%) females. Numbers of the cases under twelve months of age were 38 (63.33%) while the distribution of the rest is shown in table-2. Clinical presentation in these children is shown in tables 3 and 4 while table-5 shows the radiological findings.

Malnutrition was present in 24 (40%) children. All children in this study were from sunnier climes. Housing in disadvantageous position for sunrays was predisposing factor in 15 (25%) cases. In 40 (66.66%) children weaning was either not started, delayed, or inadequate. In 51 (85%) children radiological evidence of rickets (metaphyseal splaying/fraying, cupping at the lower ends of radius and ulna, and decreased bone density) was present. X-ray wrist showed delayed bone age in 3 (5%) cases absent ossification centers in 9 (15%) infants more than six months old.

DISCUSSION

Vitamin D deficiency is a common problem in Pakistan as highlighted in different studies. In developed countries resurgence of rickets is noted among the immigrants. Mughal et al describe six cases of rickets from 1995-97, while in Copenhagen 5 cases/year of rickets were described over a 10 year period. High incidence of sub clinical rickets (without clinical signs) in immigrant children has been reported in Denmark (46% in 0-8 years and 81% in 9-16 years). Presentation of rickets in present study seems to be the tip of the iceberg as 60 cases with apparent signs of rickets were documented in a 12 months period in a single tertiary care teaching hospital.

In present study 20 (20%) cases presented with delayed motor milestones. In addition to defective skeletal maturation vitamin D deficiency causes severe muscle weakness and muscle aches and pains, which can have devastating consequences to the child health. Similarly 18.33% cases, had recurrent lower respiratory tract infections. High frequency of pneumonia has been reported in multiple national and international articles. In fact T and B lymphocytes have receptors for 1,25(OH)\_2\_D. Vitamin D deficiency may predispose to different bacterial infections including pneumonia. 1-25 (OH)\_2\_D\_3 plays important role in immune modulation. Yener et al have reported more episodes of bacterial infections in children with vitamin D deficiency as compared to healthy children. Recurrent diarrhea was presenting complaint in 12 (20%) cases. Diarrhea is common in developing countries like Pakistan due to poor hygiene, non-availability of clean water and malnutrition. In present study, symptoms improved with vitamin D supplementation. Hameed et al, Jamal et al and Khattak et al have also reported association of rickets with recurrent or chronic diarrhea. Non-febrile fits were present in 3 (5%) cases. In present study all children presenting with fits were less than 24 months. Hypocalcaemia is more common in initial stages of nutritional rickets, especially during rapid growth period. Hameed et al have reported 10 % of children with non-febrile fits suffering from nutritional rickets.

In different studies multistory buildings and heavy atmospheric pollution of metropolis
obstructing sunrays have been mentioned as a risk factor for vitamin D deficiency rickets. In present study all the children were from sunnier clime of hilly areas. In 25% of the cases housing was at a disadvantageous position for sunshine. Other studies have also reported prevalence of rickets in sunnier climes.

Dark skin complexions may be the predisposing factor in present study (75% children had dark complexions). Most cases of nutritional rickets in United Kingdom have been reported in children of Black or Asian origin. Children with dark skin are as much capable of synthesizing vitamin D, but to do so require greater exposure to the ultraviolet rays.

In 15 (25%) children skin complexions were fair. These children belonged to hilly areas of district Kohistan and Mansehra facing extremes of cold. In these areas wood is used to generate the heat, with formation of huge smoke that hides the fair skin complexion and because of danger of pneumonia parents are reluctant to give bath to their children. Heavy clothing obstructing the ultraviolet rays is also a risk factor.

In a study conducted in slum areas of Karachi 99% of the children with nutritional rickets were malnourished. In present study 24 (40%) children were underweight according to Gomez classification of malnutrition. Malnutrition has been reported in literature as a contributing factor for nutritional rickets.

In this study 14 (23.33%) children were below 6 months of age while 38(68.33%) children were below 13 months. Poor maternal vitamin D status during pregnancy, in addition to other factors, may be important risk factor in these babies. Thick dark veils and habit of indoor staying contributes to vitamin D deficiency in pregnant and lactating mothers.

The clinical signs of the rickets (widened wrists, rickety rosary of costochondral junctions, and bowing of the legs) were present in 40 (66.66%) children while Hameed et al have reported these clinical signs in 70% of the children with nutritional rickets.

In present study 51(85%) children had radiological findings of rickets, while these findings were detected in 73.84% , 38.09% and 100% in different studies.

In 3(5%) children bone age was delayed ((Fig-1), while no ossification center was present in wrist joint x-ray in 9(15%) children (age more than six months) (Fig-2). Glerup et al have reported delayed bone age in 11.76% of the children with nutritional rickets.

Figure-1: Delayed Bone age in a 5 years old child with rickets. Only 3 ossification centers are present at carpal bones on X-ray left wrist joint

Figure-2: No ossification center is visible at carpal bones in X-ray of left wrist joint is this 7 months old infant

CONCLUSION

Non-infectious rickets remains an important preventable illness, which predisposes to infectious diseases like bacterial pneumonias, recurrent diarrheas and bone deformities in cases of late presentation. Nutritional rickets in sunny clime of Hazara Division presenting with multiple clinical presentation is predisposing factor for different childhood illnesses. Lack of awareness of importance of sun exposure, malnutrition and antenatal factors were found to be the predisposing factors for nutritional rickets.
